- Go programs compile to a single native binary and do not require any additional software to be installed in order to run them

- Using a single native binary makes it a lot easier to distribute programs written in Go.

Go Module:-

- Go project called a module.

- The main package in a Go module contains the code that starts a Go program.

- Go imports only whole package. You can't limit the important to specific types, functions, constants, or variables within a package.

- All Go programs start from the main function in the main package. You declare this function with func main() and a left brace.

* The Semicolon Insertion Rule:-

Go developers should never put the semicolons in themselves. The Go compiler adds them automatically.

- The semicolon insertion rule and the resulting restriction on brace placement is one of the things that makes the Go compiler simpler and faster, while at the same time enforcing a coding style.

- If the last token before a newline is any of the following, the lexer inserts a semicolon after the token:

- An identifier which includes words like int4 float64)
- A basic literal such as a number or string constant.
- one of the token : break, continue, fallthrough, return, ++, --,), or }

With this simple rule in place, you can see why putting a brace in the wrong place breaks. If you write your code like this:

```
func main()
{
    fmt.Println("Hello, world!")
}
```

the semicolon insertion rule sees the) at the end of the `func main()` line and turns that into:

```
func main();
{
    fmt.Println("Hello, world!");
};
```
